Folders and Tasks

1.1 Folders
1.2 Why Use Folders?

One reason to use folders is to reduce class dependencies and improve modularity. Each set of data has a producer class and one or many consumer classes. When using folders, the producer class places a pointer to the data into a folder, and the consumer class retrieves a reference to the folder.

The consumer can access the objects in a folder by specifying the path name of the folder.

Here is an example of a folder’s path name:

//root/Event/Hits/TCP

One does not have to specify the full path name. If the partial path name is unique, it will find it; otherwise it will return the first occurrence of the path.

The first diagram shows a system without folders. The objects have pointers to each other to access each other’s data. Pointers are an efficient way to share data between classes. However, a direct pointer creates a direct coupling between classes. This design can become a very tangled web of dependencies in a system with a large number of classes.

In the second diagram, a reference to the data is in the folder and the consumers refer to the folder rather than each other to access the data. The naming and search service provided by the ROOT folders hierarchy provides an alternative. It loosely couples the classes and greatly enhances I/O operations. In this way, folders separate the data from the algorithms and greatly improve the modularity of an application by minimizing the class dependencies.

In addition, the folder hierarchy creates a picture of the data organization. This is useful when discussing data design issues or when learning the data organization. The example below illustrates this point.

1.3 How to Use Folders

Using folders means to build a hierarchy of folders, posting the reference to the data in the folder by the producer, and creating a reference to the folder by the user.

1.3.1 Creating a Folder Hierarchy

To create a folder hierarchy you add the top folder of your hierarchy to //root. Then you add a folder to an existing folder with the TFolder::AddFolder method. This method takes two parameters: the name and title of the folder to be added. It returns a pointer of the newly created folder.

The code below creates the folder hierarchy shown in the browser. In this macro, the folder is also added to the list of browsable. This way, it is visible in the browser on the top level.
{ // Add the top folder of my hierarchy to /root
 TFolder *aliroot=gROOT->GetRootFolder()->AddFolder("aliroot",
  "aliroot top level folders");

 // Add the hierarchy to the list of browsables
 gROOT->GetListOfBrowsables()->Add(aliroot,"aliroot");

 // Create and add the constants folder
 TFolder *constants=aliroot->AddFolder("Constants",
  "Detector constants");

 // Create and add the pdg folder to pdg
 TFolder *pdg = constants->AddFolder("DatabasePDG","PDG database");

 // Create and add the run folder
 TFolder *run = aliroot->AddFolder("Run","Run dependent folders");

 // Create and add the configuration folder to run
 TFolder *configuration = run->AddFolder("Configuration",
  "Run configuration");

 // Create and add the run_mc folder
 TFolder *run_mc = aliroot->AddFolder("RunMC",
  "MonteCarlo run dependent folders");

 // Create and add the configuration_mc folder to run_mc
 TFolder *configuration_mc = run_mc->AddFolder("Configuration",
  "MonteCarlo run configuration");
}
1.3.2 Posting Data to a Folder (Producer)

A $\text{TFolder}$ can contain other folders as shown above or any $\text{TObject}$ descendents. In general, users will not post a single object to a folder; they will store a collection or multiple collections in a folder. For example, to add an array to a folder:

```cpp
TObjArray *array;
run_mc->Add(array);
```

1.3.3 Reading Data from a Folder (Consumer)

One can search for a folder or an object in a folder using the $\text{ROOT}::\text{FindObjectAny}$ method. It analyzes the string passed as its argument and searches in the hierarchy until it finds an object or folder matching the name. With $\text{FindObjectAny}$, you can give the full path name, or the name of the folder. If only the name of the folder is given, it will return the first instance of that name. A string-based search is time consuming. If the retrieved object is used frequently or inside a loop, you should save a pointer to the object as a class data member. Use the naming service only in the initialization of the consumer class. When a folder is deleted, any reference to it in the parent or other folder is deleted also.

```cpp
conf=(TFolder*)gROOT->FindObjectAny("/aliroot/Run/Configuration");
// or ...
conf=(TFolder*)gROOT->FindObjectAny("Configuration");
```

By default, a folder does not own the object it contains. You can overwrite that with $\text{TFolder}::\text{SetOwner}$. Once the folder is the owner of its contents, the contents are deleted when the folder is deleted. Some $\text{ROOT}$ objects are automatically added to the folder hierarchy. For example, the following folders exist on start up:
CHAPTER 1. FOLDERS AND TASKS

//root/ROOT Files with the list of open Root files
//root/Classes with the list of active classes
//root/Geometries with active geometries
//root/Canvases with the list of active canvases
//root/Styles with the list of graphics styles
//root/Colors with the list of active colors

For example, if a file myFile.root is added to the list of files, one can retrieve a pointer to the corresponding TFile object with a statement like:

```cpp
TFile *myFile = (TFile*)gROOT->FindObjectAny("/ROOTFiles/myFile.root");
//or...
TFile *myFile = (TFile*)gROOT->FindObjectAny("myFile.root");
```

1.4 Tasks

Tasks can be organized into a hierarchy and displayed in the browser. The TTask class is the base class from which the tasks are derived. To give task functionality, you need to subclass the TTask class and override the Exec method. An example of TTask subclasses is $ROOTSYS/tutorials/MyTasks.cxx. The script that creates a task hierarchy and adds it to the browser is $ROOTSYS/tutorials/tasks.C. Here is a part of MyTasks.cxx that shows how to subclass from TTask.

```cpp
#include "TTask.h"

class MyRun : public TTask {
  public:
    MyRun() { ; }
    MyRun(const char *name,const char *title);
    virtual ~MyRun() { ; }
    void Exec(Option_t *option="");
    ClassDef(MyRun,1) // Run Reconstruction task
  }

class MyEvent : public TTask {
  public:
    MyEvent() { ; }
    MyEvent(const char *name,const char *title);
    virtual ~MyEvent() { ; }
    void Exec(Option_t *option="");
    ClassDef(MyEvent,1) // Event Reconstruction task
  }

Later in MyTasks.cxx, we can see examples of the constructor and overridden Exec() method:

```cpp
ClassImp(MyRun)
MyRun::MyRun(const char *name,const char *title):TTask(name,title)
{
...
}
void MyRun::Exec(Option_t *option)
{
  printf("MyRun executingn");
}
```

Each TTask derived class may contain other TTasks that can be executed recursively. In this way, a complex program can be dynamically built and executed by invoking the services of the top level task or one of its subtasks. The constructor of TTask has two arguments: the name and the title. This script creates the task defined above, and creates a hierarchy of tasks.
1.4. TASKS

// Show the tasks in a browser. To execute a Task, select
// "ExecuteTask" in the context menu see also other functions in the
// TTask context menu, such as:
// - setting a breakpoint in one or more tasks
// - enabling/disabling one task, etc

void tasks() {
    gROOT->ProcessLine(".L MyTasks.cxx++");

    TTask *run = new MyRun("run", "Process one run");
    TTask *event = new MyEvent("event", "Process one event");
    TTask *geomInit = new MyGeomInit("geomInit", "Geometry Initialisation");
    TTask *matInit = new MyMaterialInit("matInit", "MaterialsInitialisation");
    TTask *tracker = new MyTracker("tracker", "Tracker manager");
    TTask *tpc = new MyRecTPC("tpc", "TPC Reconstruction");
    TTask *its = new MyRecITS("its", "ITS Reconstruction");
    TTask *muon = new MyRecMUON("muon", "MUON Reconstruction");
    TTask *phos = new MyRecPHOS("phos", "PHOS Reconstruction");
    TTask *rich = new MyRecRICH("rich", "RICH Reconstruction");
    TTask *trd = new MyRecTRD("trd", "TRD Reconstruction");
    TTask *global = new MyRecGlobal("global", "Global Reconstruction");

    // Create a hierarchy by adding sub tasks
    run->Add(geomInit);
    run->Add(matInit);
    run->Add(event);
    event->Add(tracker);
    event->Add(global);
    tracker->Add(tpc);
    tracker->Add(its);
    tracker->Add(muon);
    tracker->Add(phos);
    tracker->Add(rich);
    tracker->Add(trd);

    // Add the top level task
    gROOT->GetListOfTasks()->Add(run);

    // Add the task to the browser
    gROOT->GetListOfBrowsables()->Add(run);
    new TBrowser;
}

Note that the first line loads the class definitions in MyTasks.cxx with ACLiC. ACLiC builds a shared library and adds the classes to the Cling dictionary. See “Adding a Class with ACLiC”.

To execute a TTask, you call the ExecuteTask method. ExecuteTask will recursively call:

- the TTask::Exec method of the derived class;
- the TTask::ExecuteTasks to execute for each task the list of its subtasks;

If the top level task is added to the list of ROOT browsable objects, the tree of tasks can be seen in the ROOT browser. To add it to the browser, get the list of browsable objects first and add it to the collection.

    gROOT->GetListOfBrowsables()->Add(run);

The first parameter of the Add method is a pointer to a TTask, the second parameter is the string to show in the browser. If the string is left out, the name of the task is used.

After executing, the script above the browser will look like in this figure.
Figure 1.1: Tasks in the ROOT browser
1.5 Execute and Debug Tasks

The browser can be used to start a task, set break points at the beginning of a task or when the task has completed. At a breakpoint, data structures generated by the execution up this point may be inspected asynchronously and then the execution can be resumed by selecting the “Continue” function of a task.

A task may be active or inactive (controlled by \texttt{TTask::SetActive}). When a task is inactive, its sub tasks are not executed. A task tree may be made persistent, saving the status of all the tasks.
